I. Introduction

Chua circuit is the simplest electronic circuit which exhibits the phenomenon of chaos. It was invented by Leon Chua in 1983.

A dynamical system is said to have chaotic behaviour when despite its deterministic nature, it is not predictable. The apparent random behaviour of the system is usually governed by deterministic laws that are highly sensitive to initial conditions. A small change in initial conditions can result in widely varying results.

To exhibit chaos, a circuit must have been:

- i.) at least one locally active resistor
- ii.) at least one non-linear element
- iii.) at least three energy storage units

II. Theoretical Design

2.1 Circuit Elements and Constraints

In order to physically exhibit the phenomenon of chaos Chua decided to design a physical circuit with 3 unstable equilibrium points with further contraints that number of passive elements should be as few as possible and there should be only one non-linear resistor with

two terminals which has piecewise linear characteristic.

There must be 3 energy storage elements as the dynamical system must have at least order 3 to be chaotic. He also decided to have only one passive element in the circuit - a linear resistor.

Passive elements are the circuit elements which do not generate power but instead store or dissipate it.

Also since we want to observe oscillations, we cannot have only capacitors or only inductors as all 3 energy storage elements. There must be some combination of both. Chua preferred the combination of two capacitors and one inductor to make the circuit more cost-efficient.

2.2 Possible Configurations

With these constraints in place, there can be 8 possible configurations.

Fig 1. Possible configurations for the circuit

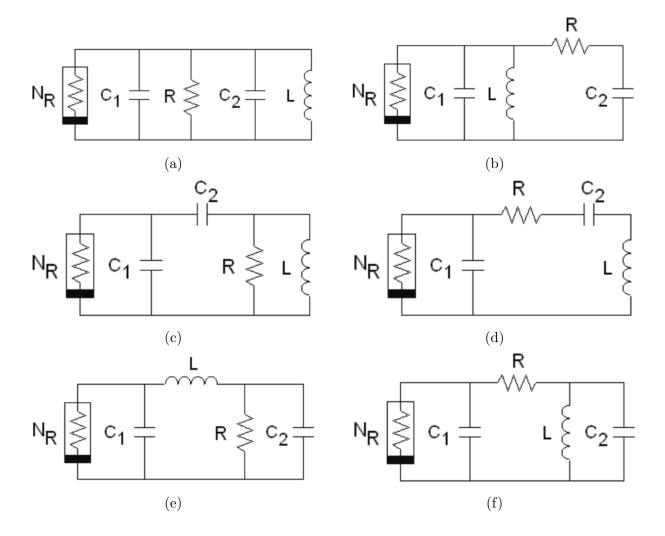

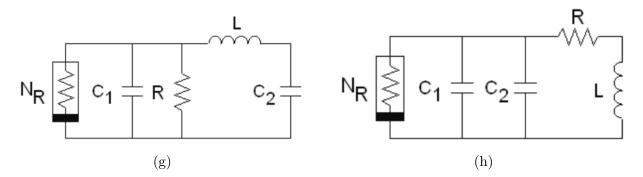

Fig 1. Possible configurations for circuit

Configuration (g) and (h) can be immediately rejected.

In (g) the characteristic of resistance R can be absorbed in the characteristics of non-linear resistor N_R . In (h) the C_1 and C_2 capacitances can be replaced by a single effective capacitor $C = C_1 + C_2$. So in both of these configurations all circuit elements do not give unique contribution. Thus they can be rejected.

For (a) and (b), the DC equilibrium calculations show that non-linear resistor gets short-circuited by the inductor. For (c) and (d), the DC equilibrium calculations show that non-linear resistor terminals are open. So all the four configurations can be rejected.

The remaining configuration (e) and (f) are both valid, but Chua selected configuration (f) because the RLC subcircuit generates oscillations.

2.3 Final Circuit

The final Chua circuit is given as follows:

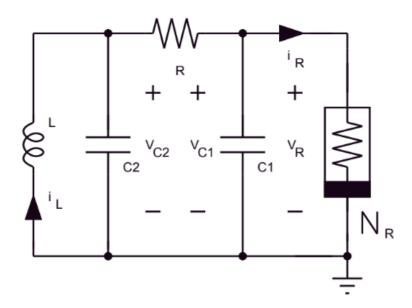

Fig 2. Chua's Circuit

III. State Equations and Simulations

3.1 State Equations

The equations of Chua's circuit are given as a system of three coupled differential equations:

$$C_1 \frac{dv_{C_1}}{dt} = G(v_{C_2} - v_{C_1}) - g(v_{C_1})$$
(1)

$$C_2 \frac{dv_{C_2}}{dt} = G(v_{C_1} - v_{C_2}) - i_L \tag{2}$$

$$L\frac{i_L}{dt} = -v_{C_2} \tag{3}$$

where, $G = \frac{1}{R}$ is the conductance, and g(x) is a piece-wise linear function. It is given as:

$$g(v) = m_0 v + \frac{1}{2} (m_1 - m_0) \left[|v + B_p| - |v - B_p| \right]$$
(4)

where,

 $m_0 \implies \text{slope of outer region}$

 $m_1 \implies \text{slope of inner region}$

 $B_P \implies$ breakpoints (both positive and negative values)

3.2 Simulation

The variables were redefined and all constants were taken to right hand side to make handling the equations easier.

$$\frac{dx}{dt} = \frac{1}{C_1} \left\{ G(y - x) - g(x) \right\} \tag{5}$$

$$\frac{dy}{dt} = \frac{1}{C_2} \left\{ G(x - y) - z \right\} \tag{6}$$

$$\frac{dz}{dt} = -\frac{y}{L} \tag{7}$$

where,

$$x \equiv v_{C_1}$$
 $y \equiv v_{C_2}$ $z \equiv i_L$

The equation q(x) remains the same as in (4).

The equations are solved numerically using Runge Kutta 4 method in Python. All plots are made using Gnuplot.

3.2.1 Python Codes

The code for RK4 is as follows:

```
1 #Chua circuit simulations
  import math
4 import handling_files
5 import numpy as np
  #RK4 to solve Chua circuit equations (a system of 3-ODEs)
  def RK4_chua(F,b,t,h,N,name):
      handling_files.append_file(name, f'\{t\} \{b[0]\} \{b[1]\} \{b[2]\} \setminus n')
      for i in range(N):
           K1=F(t,b)
11
12
           K2=F(t+h/2, b+np.multiply(K1,h/2))
14
           K3=F(t+h/2, b+np.multiply(K2,h/2))
16
           K4=F(t+h, b+np.multiply(K3,h))
17
18
           b=b+np.multiply((K1+np.multiply(K2,2)+np.multiply(K3,2)+K4), h/6)
19
           t = t + h
           handling_files.append_file(name, f'\{t\} \{b[0]\} \{b[1]\} \{b[2]\} \setminus n')
21
22
      return(1)
```

The code inputs the three differential equations as a column vector F which is a function of x, y, z and t (time). x, y and z are arranged as column vector b. For the first iterations, it has the initial values. h is the increment factor. N is the number of iterations. t_0 is the initial time value.

The 'append.file()' function saves the data points (t, x, y and z) after each iteration in a file (filename provided to function as variable 'name'). All codes for manipulation with files is as follows:

```
12 # APPEND FILE
 def append_file(x, str): #arguments = name of file, string to append
    f=open(x, 'a') #'a' ==> append file
    f.write(str)
    f.close()
17
19 #
    #WRITE AT BEGINNING (hopefully)
 def write_beginning(x, str):
    f = open(x, 'r+')
    old=f.read()
    f.seek(0)
    f.write(str + old)
    f.close()
    # it works :D
28
 # PRINT CONTENTS OF A TEXT FILE
 def print_file(x): #argument = name of file
    f = open(x, 'r')
    contents=f.read()
    print(contents)
34
36 #
```

3.2.2 Plots with Dimensionless Constants

The following values were used for the constants:

$$G = 0.7$$
 $C_1 = 1/9$ $C_2 = 1$ $L = 1/7$ $B_p = 1$ $m_0 = -0.5$ $m_1 = -0.8$

The function g(v) in (4) can be plotted using the constants.

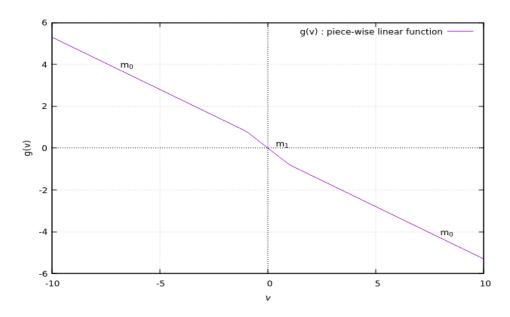

Fig 3. Three Segment Linear Function : g(v)

The code for defining the function, initial values and calling the function is:

```
# Dimensionless Chua Circuit
3 import math
4 import sys
5 import numpy as np
7 sys.path.append('/home/ashmita/Desktop/ASHMITA/APanda_Lib')
8 # importing all files at once, now we just need to write function name to
      access it
9 from APanda_Lib import *
  import chua_circuit_simulations
13 #dimensionless chua
_{14} R=1.4285 # R corresponding to G=0.7
15 C1 = 1/9
16 C2=1
_{17} L=1/7
18 Bp = 1
m0 = -0.5
20 \text{ m1} = -0.8
22 \times 0 = 0.1
y0 = 0.0
24 z0 = 0.0
t0 = 0.0
  b0 = [x0, y0, z0]
29 def Yfunc(t,b):
```

The data file obtained is plotted using Gnuplot.

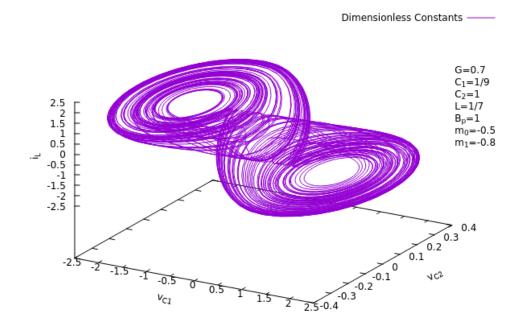

Fig 4. 3D plot of v_{C_1} vs v_{C_2} for dimensionless constants

Thus, we do obtain a double scroll attractor for the Chua Circuit. In principle, the Chua Circuit does exhibit chaotic behaviour.

3.2.3 Varying R with Dimensionful Constants

Now, we will attempt to use constants which represent actual dimensionful values and try to observe how the graph changes when we change the value of resistance R.

We will define conversion factors to relate the value of our constants to values of actual electronic circuit components. Current will be measured in Amperes(A), potential differences in Volts(V), capacitances in Farads(F), inductance in Henry(H) and resistance in Ohm(Ω). Resistivity is expressed in Siemens(S)

If we want currents of milliamperes to be in the circuit, we will adjust all current values by 1000. It will thus increase resistances and inductance by 1000, while decreasing capacitances by the same factor. Also, we can also rescale the values of time by some factor k in (3). This will leave all resistances unaffected, and all capacitors and inductors will be scaled by same factor k. For ease of using values in the code, I have chosen k to be 10^{-4} , i.e., I rescale all capacitances and inductances by 10^{-4} . This gives us the final conversion factors as:

$$R: 1 \equiv 1000\Omega = 1k\Omega$$

 $C_1, C_2: 1 \equiv 10^{-7}F = 100nF$
 $L: 1 \equiv 10^{-1}H = 100mH$
 $m_0, m_1: 1 \equiv 10^{-3}S = 1mS$
 $B_p: 1 \equiv 1V$

So, the constants used in the previous part correspond to:

$$R = 1.43k\Omega$$
; $C_1 = 11.11nF$; $C_2 = 100nF$; $L = 14.29mH$; $B_p = 1V$; $m_0 = -0.5mS$; $m_1 = -0.8mS$

We will now attempt to vary R and observe how the output changes.

The code for defining the function, initial values, varying R values and calling the function is:

```
# Varying R

import math
import sys
import numpy as np

sys.path.append('/home/ashmita/Desktop/ASHMITA/APanda_Lib')# importing all
    files at once
from APanda_Lib import *

import chua_circuit_simulations

# varying R

R = float(input('Please enter the value of R.\n'))
C1=1/9
C2=1
L=1/7
Bp=1
Bm0=-0.5
```

```
19 \text{ m} 1 = -0.8
21 \times 0 = 0.1
y0 = 0.0
23 z0 = 0.0
t0 = 0.0
b0 = [x0, y0, z0]
  def Yfunc(t,b):
      x,y,z=b
      gx=m0*x+0.5*(m1-m0)*(abs(x+1)-abs(x-1))
      Y = [(1/C1)*((1/R)*(y-x)-gx), (1/C2)*((1/R)*(x-y)+z), (-1/L)*y]
31
      return Y
32
      #
33
35 h = 0.1
_{36} N=5000
37 path="/home/ashmita/Desktop/ASHMITA/NISER Study/7th Semester/Open Lab/Non-
     Linear Circuit/Varying R/"
name=f'R=\{R\},
39 n=path+name
40 f = open(n, "w")
41 f.close()
out2=chua_circuit_simulations.RK4_chua(Yfunc,b0,t0,h,N,n)
```

Plotting the data files obtained in Gnuplot.
